Pie chart — statement shares

The pie chart compares the six statement-level mean agreement values after normalizing them to a common total. The largest slice corresponds to the statement with the highest mean. These are shares of the six averages, not shares of surveyed people.

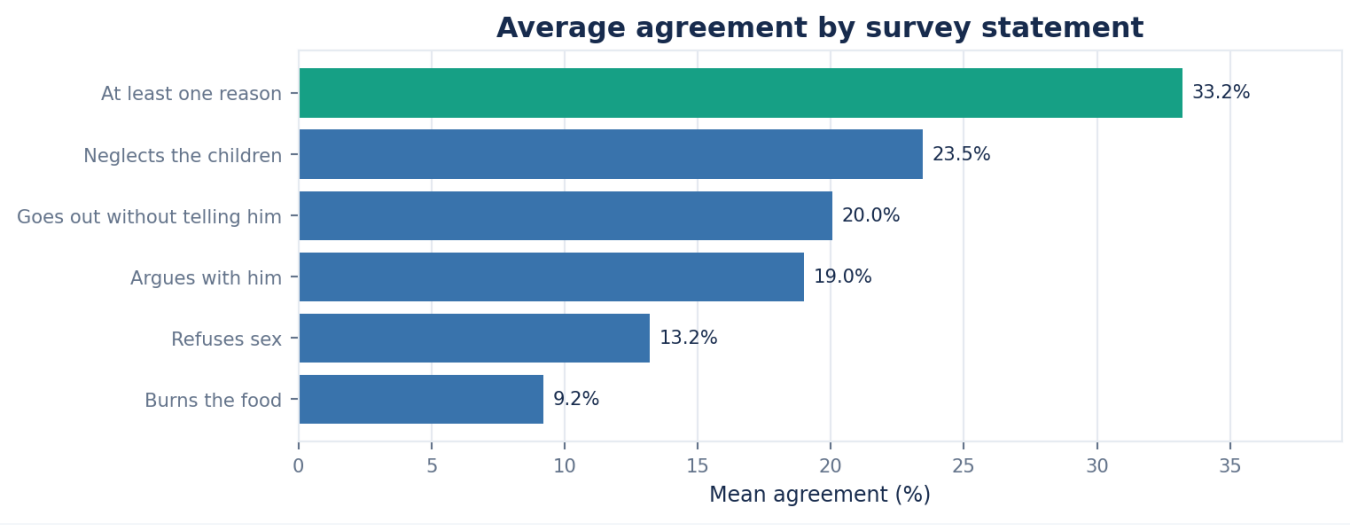

Reading note: Compare patterns in context; these are percentages of agreement, not counts of violence.

Bar chart — agreement by statement

This chart ranks the statements by their mean agreement percentage. In this dataset, “at least one specific reason” has the highest average (33.2%), while “burns the food” has the lowest (9.2%). The values describe attitudes reported in the survey.

Reading note: Compare patterns in context; these are percentages of agreement, not counts of violence.

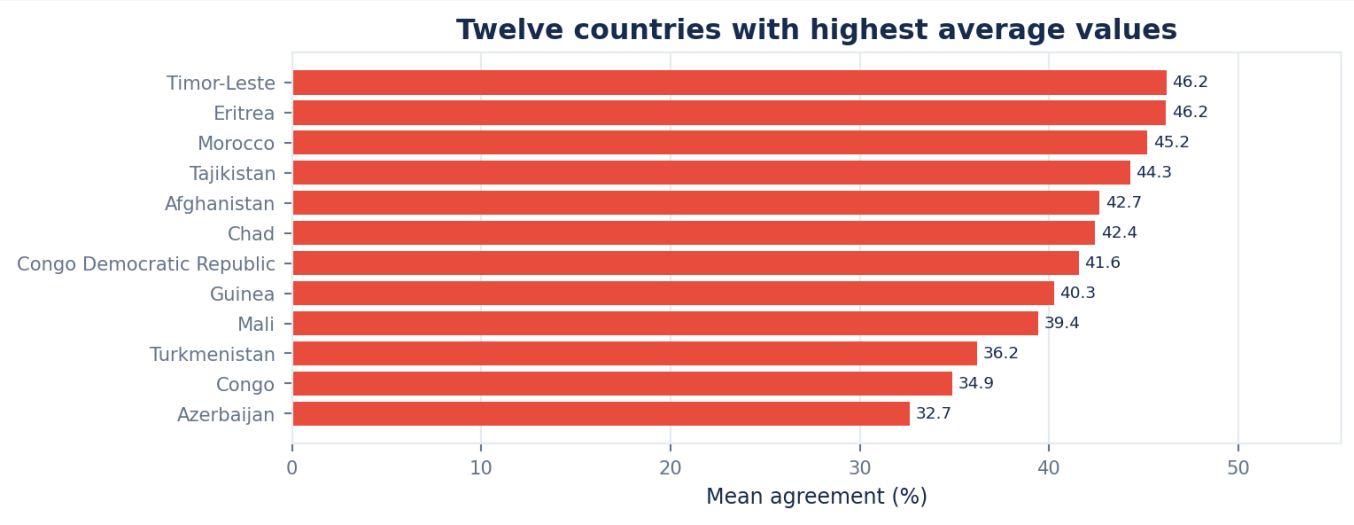

Visual analysis | Section 2 of 5

Country comparison

The horizontal bars show the twelve countries with the highest unweighted mean agreement values in the available records. Timor-Leste and Eritrea are at the top of this descriptive ranking. Country comparisons should be interpreted cautiously because respondent weights and denominators are not included in the supplied fields.

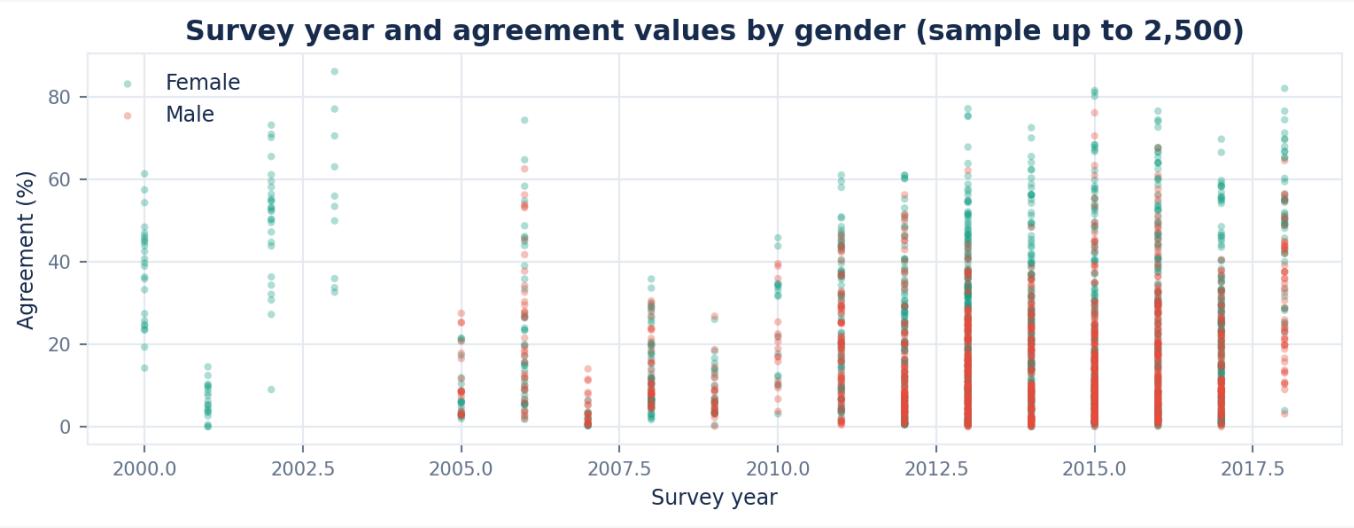

Reading note: Compare patterns in context; these are percentages of agreement, not counts of violence.

Scatter plot — year and gender

Each point represents a survey record, positioned by survey year and agreement percentage; colour distinguishes gender. The plot helps reveal spread and overlap rather than proving a time trend. For readability, up to 2,500 records are sampled for this chart only.

Reading note: Compare patterns in context; these are percentages of agreement, not counts of violence.

Line chart — annual statement averages

The lines show the annual mean agreement percentage for each statement where records are available. Gaps and changes can reflect which countries and groups were surveyed in a given year, not necessarily changes in attitudes within the same population.

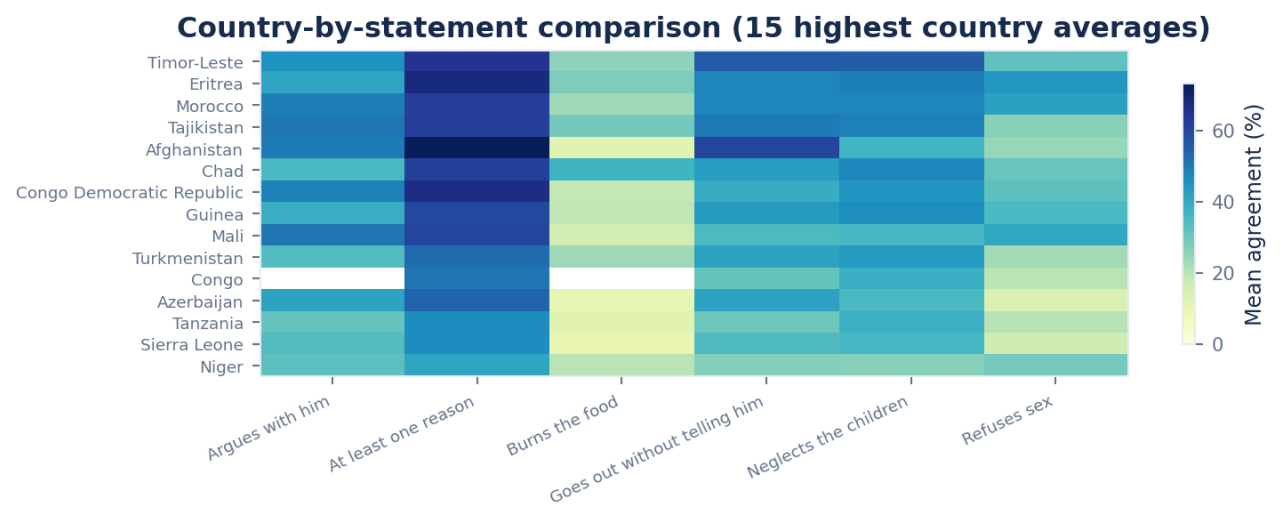

Reading note: Compare patterns in context; these are percentages of agreement, not counts of violence.

Heatmap — country and statement

The heatmap uses colour intensity to compare average agreement across statements for up to fifteen countries. Darker cells indicate higher mean agreement. It is useful for spotting patterns, but it does not adjust for differences in survey coverage or sample composition.

Reading note: Compare patterns in context; these are percentages of agreement, not counts of violence.

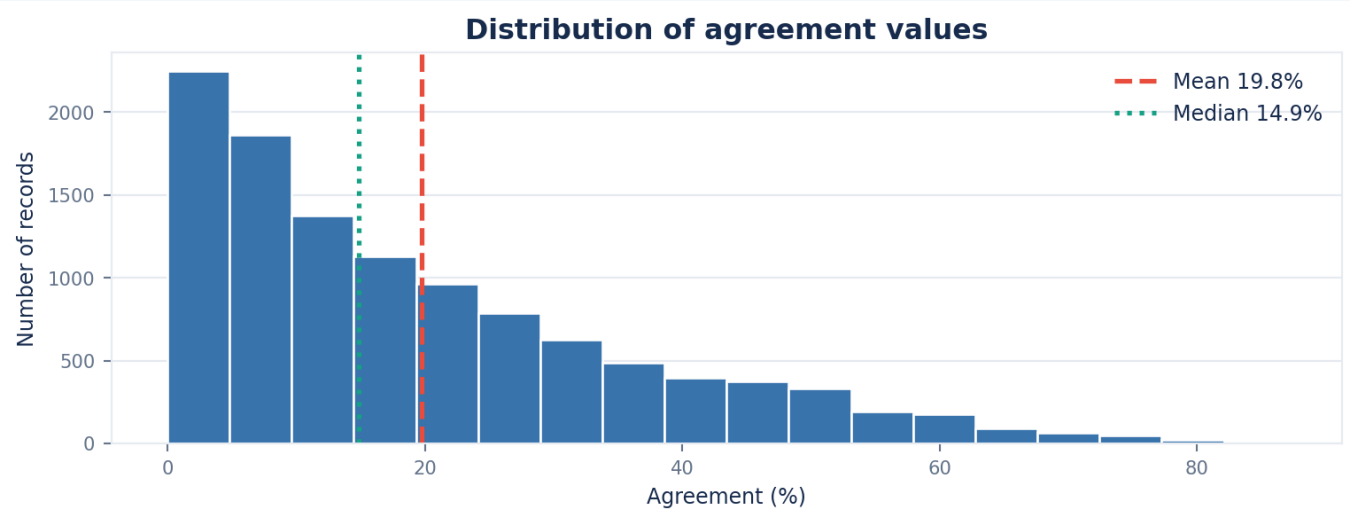

Visual analysis | Section 4 of 5

Histogram — distribution

The histogram groups valid agreement values into eighteen intervals. It shows where observations are concentrated and how widely they vary. The overall mean is 19.8% and the median is 14.9%; the mean being higher suggests a distribution with a higher-value tail.

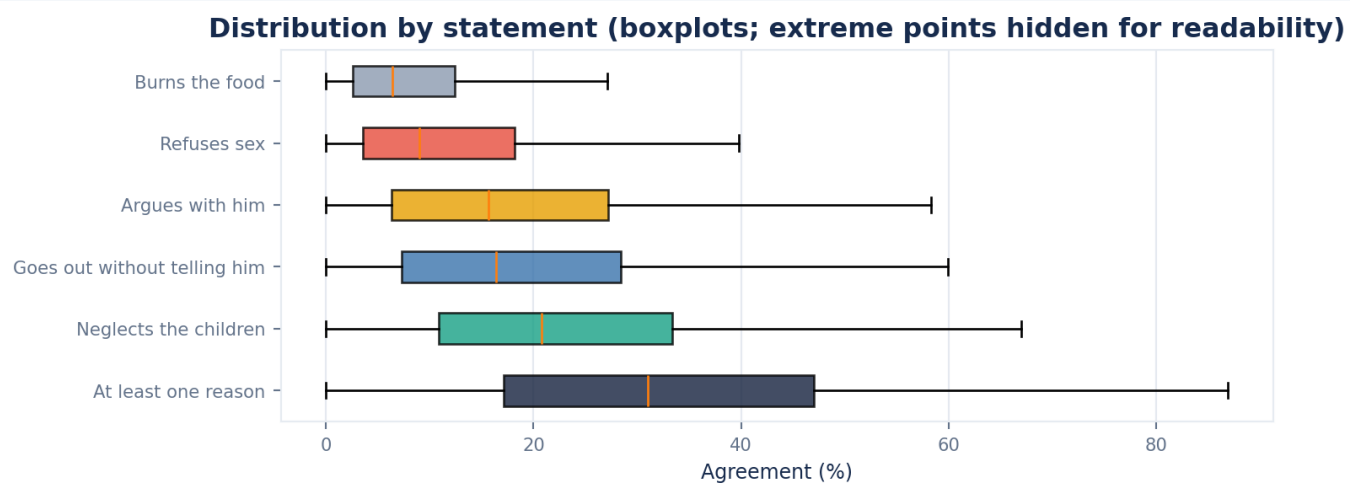

Reading note: Compare patterns in context; these are percentages of agreement, not counts of violence.

Boxplot — spread by statement

Each box summarizes the distribution for one statement: the centre line is the median, the box covers the middle half of values, and whiskers show the broader spread. Extreme points are hidden in this display to keep the comparison readable.

Reading note: Compare patterns in context; these are percentages of agreement, not counts of violence.

Area chart — yearly averages

The filled lines provide another view of yearly average agreement by statement. They emphasize the changing profile across years, but should not be read as a continuous panel study: the dataset combines different survey groups and countries across years.

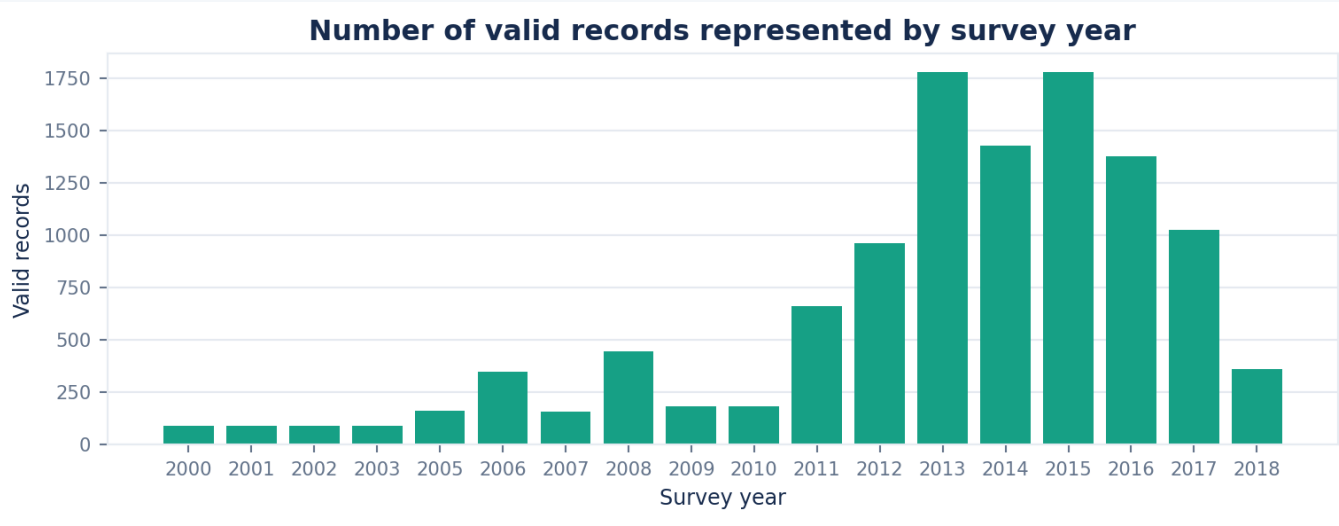

Reading note: Compare patterns in context; these are percentages of agreement, not counts of violence.

Survey coverage by year

This supporting chart counts records with both a numeric agreement value and a usable survey year. Coverage varies substantially across years. Therefore, year-to-year averages may be affected by changing data availability and should not be interpreted as a controlled trend.

Reading note: Compare patterns in context; these are percentages of agreement, not counts of violence.

Conclusion and implications

Synthesis of the descriptive patterns in the supplied dataset

1. Overall pattern

The dataset contains 12,600 records across 70 countries, six survey statements and survey years from 2000 to 2018. After excluding rows without a usable numeric Value or survey year, 11,187 records remain for the chart calculations. The unweighted mean agreement value is 19.8% and the median is 14.9%.

2. Statements with higher agreement

The statement “for at least one specific reason” has the highest average agreement (33.2%). It is followed by “if she neglects the children” (23.5%) and “if she goes out without telling him” (20.1%). “If she burns the food” has the lowest average (9.2%). These findings indicate that the justifications represented in the survey are not equally accepted across the six statements.

3. Differences between groups and countries

The available records show a higher unweighted average for female respondents (22.9%) than for male respondents (15.9%). Country averages also vary considerably; the highest observed country-level averages include Timor-Leste (46.2%) and Eritrea (46.2%). These are descriptive comparisons and do not establish why differences occur.

4. Time and coverage

The yearly charts show substantial variation in the number of available records across survey years. Some years have far more observations than others, and the set of countries and demographic groups may change. For that reason, apparent year-to-year increases or decreases should not be treated as evidence of a population-wide change without a harmonized longitudinal design.

5. Interpretation and limitations

The Value field measures the percentage of people in the relevant survey group who agree with a statement that is sometimes used to justify wife-beating. It is an attitude measure, not a measure of actual violence, incidence or prevalence. The supplied fields do not provide respondent counts or survey weights for the calculations presented here; averages are therefore unweighted. Missing or non-numeric values are excluded. Pie slices are shares of statement averages, not respondent shares.

6. Practical use

The findings can support further investigation, public-awareness planning and the identification of topics or settings for deeper analysis. They should be combined with appropriately weighted survey estimates, contextual research and direct evidence on violence and services before informing operational targets or evaluating interventions.
